Catalogue 999337 - 06/2009

In preparing our new catalogue we have made every effort to present the information in a clear and concise manner. We hope you will find the format to be satisfactory, enabling you to quickly locate any required information. However if you have any suggestions for improvements we would be very pleased to receive them via our representative or direct to SUMITOMO CYCLO EUROPE.

The New HSM gearbox is Sumitomo's new range of shaft mounted speed reducers. In general the gearbox is designed to be mounted directly on the machine shaft of the application and restrained by the use of a torque arm or flange thus eliminating the need for a coupling or chain drive. Along with the ratios available a wide selection of output speeds are achievable with the use of a belt drive to the input shaft.

Alternatively the gearbox can be driven directly from a hydraulic or electric motor using an input flange adapter. The new design incorporates many features as standard that were previously available as options. This new generation of gearboxes is available in thirteen case sizes achieving a maximum output torque of 44,000 Nm.

1 Case Design - The gear case is manufactured from grey cast iron, precision bored and dowelled to ensure accurate assembly. There are thirteen case sizes available.

4 Oilseals - Oilseals are metal reinforced double lipped gaiter spring type as standard and taconite seals are available for harsh environments. All seals are available world wide.

2 Gears - The gears are helical designed to DIN/ISO and AGMA standards with a 25 degree pressure angle. They are manufactured from alloy steel, gas carburised and hardened, shaved and honed (profile ground on selected sizes) They are available in up to four ratios 5, 13, 20 and 25:1.

5 Shafts - Shafts are machined from alloy steels and are precision ground on journals, gear seating and extensions. Tolerance and keyways conform to ISO standards.

3 Bearings - The bearings used conform to the ISO dimension plan and are available world wide. The high speed and intermediary shafts are designed with roller bearings. The low speed shaft deep groove ball bearings, with taper roller bearings as an option.

6 Output hubs - Output hubs are available with Taper Grip® or parallel bore, in metric or imperial. A wide choice of output bore diameters are available, see pages 22-23 for details. Alternative bores not listed can be considered.

10 Plugs - The plugs are supplied with an integral sealing washer. The casing is machined for an excellent sealing surface.

7 Input shafts - Input shafts are available in both metric and imperial dimensions to ISO standards.

11 Torque arm - The torque arm can be mounted on the casing using one of the two dedicated casing points thus avoiding the need to remove any case half fixings. The turnbuckle design allows for quick and easy adjustment of the belt system.

8 Breather plug - The breather plug is supplied with an integral sealing washer and built in non return valve.

9 Shaft End Caps - The rubberised shaft end caps are self sealing to standard ISO housing dimensions.

12 Backstop - The backstop is available for all sizes and ratios, and can also be retrofitted once the unit has been supplied.

13 Flange mounting - Is suitable for flange mounting directly to a machines framework by use of the tapped holes around the output hub. This flange mounting may permit the omission of a bearing from the application.

The HSM can be secured to the driven shaft by means of the Taper-Grip® bush which will transmit the torque and shock overload capacity of the selected gearbox.

The Taper-Grip® bush is a unique shaft locking system that overcomes the difficulties which can be experienced with other methods of securing the hub to the machine shaft.

The Taper-Grip® bush allows for easy assembly and disassembly of the shaft mounted speed reducer, and because it generally does not use a key or keyway it avoids any type of fretting and corrosion.

The principle of using tapers to secure power transmission components has been established for many years and the Taper-Grip® bush system is based on well known locking capabilities of conventional taper fixings.

Features

- Requires no key or keyway.
- Resistant to fretting corrosion.
- Easy to assemble and position the HSM to the driven shaft.
- The bush can be used from either side of the gearbox as standard.
- Allows for the driven shaft diameter tolerances to be h11.
- Easy to remove the HSM from the driven shaft.
- Both metric and imperial shaft bores available.
- Wide selection of shaft diameters can be used.
- Taper-Grip® bush can be used with existing keyed shafts.

The Taper-Grip® bush has a series of short tapers in the form of a continuous helix. Figure 1 illustrates this and demonstrates how an optimum friction angle is used to reduce the radial dimension to a minimum.

The tapers are machined on the hub of the gearbox and the Taper-Grip® bush in the form of shallow screw threads, which enable the bush to be installed from either side of the gearbox. The bush is secured with screws acting against the wedging tapers on the screw threads.

The locking system is designed to secure the shaft mounted speed reducer to the driven shaft and provides a means to transmit the torque without the use of a key or keyway.

The bush can easily be installed on existing shafts that may already have a keyway, in which case the key will not be required.

figure 1

The ease of using the Taper-Grip® Bush

**Picture 1**

- 1 The only tools required for fitting the HSM gearbox with Taper-Grip® bush to the application is an allen key and torque wrench. The driven shaft needs to be in good condition, but no lubrication is necessary for the fitting of the gearbox to the shaft. The shaft must be free of any oil or grease.

- 2 The bush is fitted to the HSM before being offered to the application. It can then be slid on to the shaft with ease. The Taper-Grip® bush can be used on existing keyed shafts. There is no need to cover the existing keyway.

**Picture 2****Picture 3**

- 3 Once the HSM is in position, the allen key is used to tighten the cap head screws in the Taper-Grip®. These should be tightened to the set values.

**That's how easy it is to use the
Taper-Grip® bush!**

Gearbox Selection Procedure

Method A

(i) Service Factor

From page 10 locate the application type and, from the daily operational hours required, select the load classification (I, II or III).

(ii) Unit Selection

Refer to Class I, II or III selection tables on pages 11 through to 13. From the motor power and output speed required, select the unit size and ratio.

Note:

Gear units are momentarily capable of transmitting twice (2x) the rated capacity on start or during operation. For applications where momentary loads exceed a peak of 200% overload, the motor power used in the selection tables may be obtained by dividing the peak power by two.

Method B

(I) Service Factor

From page 10 locate the application type and, from the daily operational hours required, select the load classification (I, II or III). Using the table on page 10, read the service factor (fn1) associated with the load classification.

(ii) Design Power

Multiply the absorbed power (P1) (or motor power if absorbed power not known) by the service factor chosen in step (I). This represents the design power (Pd)

$$P_d = P_1 \times f_{n1}$$

(iii) Unit Selection

Using the value from step (ii), refer to the power rating tables on pages 14 and 15 and select the correct size of unit.

The choice of single or double reduction gearbox will be determined by the output speed required. The normal operating speeds for each of the gearboxes may be observed in the power rating tables.

Gearbox Selection Procedure - Examples

A Taper-Grip® Shaft Mounted Speed reducer is required for a uniformly loaded elevator which absorbs 3.6kW at 50 rpm. The prime mover is a 5HP (4kW) 4 pole direct on line start electric motor. The application requires the drive to run 24 hours/day.

Method A

(i) Service Factor

From page 10 the application type and operational hours result in a load classification of II.

(ii) Unit Selection

Referring to Class II selection tables on page 12, a motor power of 5HP and output speed of 50 shows the required unit is 115-25, 115-20 or 115-13.

Method B

(i) Service Factor

From page 10 the application type and operational hours result in a load classification of II. Using the table on page 10 the service factor is determined as:-

$$f_{n1} = 1.4$$

(ii) Design Power

The absorbed power $P_1 = 3.6$ is multiplied by the service factor (fn1) to give the design power:-

$$\begin{aligned} P_d &= 3.6 \times 1.4 \\ &= 5.04 \text{ kW} \end{aligned}$$

(iii) Unit Selection

Locate the output speed in the first column of pages 14 or 15 and read across until the unit power exceeds the design power. A double reduction unit size 115 is selected with a rated power of 6.48 kW.

Power / Torque Conversions

Th = Torque (ft.lbf)	Tm = Torque (Nm)
Ph = Power (HP)	Pm = Power (kW)
n = speed (rpm)	

$$P_h = \frac{(T_h \times n)}{5250}$$

$$P_m = \frac{(T_m \times n)}{9550}$$

To calculate the allowable overhung load on the input shaft at any position, first establish the maximum load at the mid shaft position for the unit size and input speed required (Table 1). Divide this load by the factor from Table 2 corresponding to the actual position of the load along the input shaft

Table 1

Unit Size	Input Speed 'rpm'

H S M Drive Options

To avoid the design and manufacture of a separate support for the motor when using a belt drive, a rigid support for the driving motor is available.

The motor mounts have been designed to fit onto any side of the HSM gearbox. This permits the use of various belt centre distances, easy belt tensioning and avoids alignment problems.

The motor mounts are available to accommodate a wide range of motor frame sizes and types, including IEC and NEMA.

A drilling template is provided to indicate the size and position of the holes required to suit the motor selected.

Unit Size	AV		AH		B	CV	CH	D

107	144.5	139.5	124.5	108.5	91.5	-	-	-	-	-	-
115	-	153	138	122	105	98	-	-	-	-	-
203	-	-	165.5	149.5	132.5	125.5	-	-	-	-	-
207	-	-	191	174	158	151	112	-	-	-	-
215	-	-	-	215.5	198.5	191.5	152.5	103.5	-	-	-
307	-	-	-	234.5	217.5	210.5	171.5	122.5	109.5	-	-
315	-	-	-	-	241	234	195	146	133	122	-
407	-	-	-	-	-	-	234	185	172	160	114

Note: Dimension E is measured from front motor mounting bolt to output hub face
this information allows the user to calculate the position of the motor cowl

To determine the optimum belt length when using a motor mount, first calculate the centre distances as follows:

$$\begin{aligned} XV/XH \text{ min} &= \text{Motor Frame Size} + 'AV/AH \text{ min}' \\ XV/XH \text{ max} &= \text{Motor Frame Size} + 'AV/AH \text{ max}' \end{aligned}$$

A belt length should be selected which gives a centre distance equal to or slightly larger than the 'XV/XH min' and smaller than the 'XV/XH max' values determined above.

The screw conveyor adapter allows the use of a standard HSM gearbox to fit directly onto the trough end of a screw conveyor.

The screw conveyor adapter has been designed to the CEMA (Conveyor Equipment Manufacturers Association) standards.

The cast iron four bolt mounting adapter is fitted with double lip seals as standard.

For abrasive environments, the design allows for the use with a packing gland seal. This can be adjusted as the seal wears, and makes for easy removal and replacement without trough or the gearbox being removed.

The HSM is fitted with taper roller bearings when used with this adapter to take the thrust load from the screw conveyor, and

this eliminates the need for an external thrust bearing.

The adapter may be used in any position, including horizontal, inclined and vertical with the movement of the appropriate breathers and filler plugs on the HSM gearbox.

The drive shafts are made from high alloy steel, three bolt drilled and the taper ensures a simple installation.

Other options such as stainless steel are available upon request.

Often the unit will be used with a motor mount but, in the event that belts are not be used, the HSM can be supplied with a directly driven input shaft, such as the IEC adapter.

H S M Drive

Hydraulic Options

As well as using belt drives on the input shaft, the HSM can be hydraulically driven.

The HSM can be provided with an adapter flange to allow hydraulic motors to be attached to the input of the gearbox.

Motorised Input Units

Like the hydraulic motor configuration, the HSM can be supplied with IEC or Nema flange adapters to fit motors directly to the gearbox.

This allows the HSM to be used as a geared motor, and avoids the use of belts, pulleys or input guards.

Backstop

The HSM can be fitted with a mechanical backstop to prevent reverse rotation.

The backstop is internally mounted on the input shaft. It is supplied separately so the correct rotation can be observed at the application. It is quickly and easily fitted and can be retrofitted to any unit. No additional lubrication is necessary, as it uses the gearbox oil.

Harsh Environment sealing

For added protection against dust, dirt and moisture, the HSM can be fitted with taconite seals for harsh environments (please advise when ordering)

The unit can also be fitted with increased ingress protected breathers, for example, as used in the cement industry.

Warranty

Standard warranty is two years from date of despatch from the factory.

Service

Full application and technical support service is available for the range of products covered by this catalogue.

For details please contact your nearest Sumitomo sales office address at the rear of this catalogue. Look at <http://www.sumitomo-cyclo.com>, or alternatively e-mail:

marketing@sumitomo-cyclo.com

Full application and technical support service is available for the range of products covered by this catalogue.

Signature Service

Extended warranties are available to all our customers who purchase gearboxes already supplied with lubricant for their application.

This service reinforces Sumitomo's partnership with our customers, to extend the life of the product by condition monitoring techniques and service visits.

Sumitomo's 'Signature Service' partnership can be tailored to meet customer requirements.

SUMITOMO
CYCLO EUROPE

Mobil

Other Sumitomo drive solutions

For high ratios or lower output speeds, and other design drive solutions Sumitomo have a range of alternative products such as:

Helical Buddy Box (HBB)

An integral item within Sumitomo's unique Cyclo range of gearmotors, the HBB is a Cyclo driven HSM reducer incorporating the distinctive benefit of 500% shock overload.

Paramax

Incorporating monoblock and split case designs available in a range of 24 sizes, the Paramax range offers greater options and torque capacity increases to 560,000 Nm.

H S M Drive Installation

IMPORTANT - For Taper-Grip[®] installation see page 40.

Study these instructions carefully before installing and operating the drive. Make sure that this information is readily available to all persons involved in the operation and maintenance of the drive. All appropriate safety regulations must be observed when installing a drive. Suitable safety covers or guarding must be provided for all rotating shafts. The drive is designed exclusively for use as specified in the catalogue, any other use is considered improper. The manufacturer accepts no liability for damage as a result thereof.

Before switching on or starting up the machine, make sure that nobody can be endangered by the machine/system startup. Own modifications and/or alterations which affect the safety of the drive are not permitted. Spare parts (see page 46) must comply with the technical requirements specified by SUMITOMO CYCLO DRIVE EUROPE. This is always ensured with original spare parts.

1. Ensure that the shaft onto which the reducer is to be mounted and the reducer bore are clean and free from burrs. Liberally smear the shaft and reducer bore with the contents of the tube which accompanies the reducer. This acts as a lubricant to aid mounting and facilitates easy removal by prevention of fretting and atmospheric corrosion. If the box is to be used with a bushed bore the bushes should now be fitted. Two bushes are supplied, one plain and one split.

The plain bush should always be positioned at the side opposite the input shaft. The split or keyway in the remaining bush must align with the hub keyway.

The bushes can be held in position by inserting the screws found at 120° to the keyway into the bush, care should be taken not to have the screws protruding through the bush. The screws should be fitted as indicated on the leaflet supplied with the bushes.

2. Slide the reducer onto the driven shaft which must pass through the full width. A key is supplied with the split bush, this should now be fitted. A keywayed bush should be fitted with standard section side fitting keys. Do not use taper or top fitting keys. Tighten all four screws onto the driven shaft.

3. Install pulley on input shaft as close to the reducer as possible. See fig. 1.

4. Install motor and V-Belt drive with the belt pull at approximately 90° to the centre line between driven and input shafts. See fig. 2. This will permit tensioning of the V-Belt drive with the torque-arm, which should preferably be in tension.

5. Install torque-arm on reducer by placing the forked rod end over the suitable torque-arm case bolt hole and inserting the bolt supplied. Tighten the nut/bolt to the torque stated on page 39.

6. Install torque-arm fulcrum on a rigid support so that the torque-arm will be at approximately right angles to the centre line through the driven shaft and the torque-arm case bolt. See fig. 3. Make sure there is sufficient take up in the turnbuckle for belt tension adjustment.

7. Fill with suitable lubricant as detailed on page 41.

Keep close **Figure 1**

Figure 2

Figure 3

This angle should be a right angle but may vary up to a maximum of 15° either way

Torque arm and belt take up

N.B. Backstops: A backstop for mounting inside the reducer to prevent reversal of direction is available for all reducers. For installation instructions see page 42.

REMOVING PARALLEL BORE REDUCER FROM SHAFT

Loosen screws in output hub. Using any suitable three or four point hub drawer, engage suitable extractor studs in the tapped case holes around the output hub and remove the gearbox by screwing down on the shaft.

IMPORTANT

Using tools normally found in a maintenance department, the reducer can be dismantled and re-assembled. Cleanliness is very important to prevent the introduction of dirt into the bearings and other parts of the reducer. A tank of clean solvent, an arbor press and equipment for heating bearings and gears should be available for shrinking these parts on the shafts.

Rubbing type oilseals are fitted and great care should be taken during dismantling and re-assembling to avoid damage to the rubbing surfaces.

The keyseat in the input shaft and the six holes in the output hub should be covered with tape or other suitable material. Any burrs on shaft or hub surfaces should be carefully removed before fitting seals.

We are prepared to repair reducers for customers who do not have proper facilities or who do, for any reason, desire factory service.

An estimate for the cost will be sent after examination and before the repair is begun.

ORDERING PARTS

When ordering parts for a reducer specify Reducer Size, Serial No., part name, code number and quantity required. It is strongly recommended that when a pinion or gear is replaced the mating gear or pinion be replaced also.

If the large gear on the output hub must be replaced, it is recommended that an output hub assembly of a gear assembled on a hub be ordered to secure undamaged surfaces on the outer hub where the oilseals rub. However, if it is desired to use the old output hub, press the gear and bearing off and examine the rubbing surfaces under the oilseal carefully for possible scratching or other damage resulting from the pressing operation.

To prevent oil leakage at the shaft oilseals, the smooth surface of the output hub must not be damaged. If any parts must be pressed from a shaft or from the output hub, this should be done before ordering parts to make sure that none of the bearings or other parts are damaged on removal.

Do not press against the outer race of any bearing. Because old shaft oilseals and gaskets may be damaged in dismantling, it is advisable to order replacements for these parts.

Torque arm tightening torques

HSM Size	015 to 103	107 to 115	203 to 407	415	507	608
Torque (Nm)	20	30	80	277	480	950

NOTE: Satisfactory performance depends on proper installation. Therefore all instructions must be carefully followed.

FITTING THE REDUCER TO THE SHAFT

1. Check the size and condition of the shaft to which the reducer will be fitted. Maximum tolerance is h11 although this should be improved upon where possible. Ensure the shaft and Taper-Grip® bush bore are free from burrs and corrosion. Clean both bore and shaft with solvent to remove all traces of grease and oil.

2. Lightly oil the screws and insert into the Taper-Grip® bush ensuring they do not project beyond the rear face.

3. Fit the thrust collar onto the Taper-Grip® bush, ensuring it is located on the spigot immediately behind the flange. Screw the Taper-Grip® bush into the hub in a clockwise direction until the thrust collar is trapped between the flange and the reducer hub.

4. Unscrew the bush until a gap of approx. 1mm is seen between the flange and the thrust collar (see diagram). Tighten all screws until they are finger tight. On reducers with a keyslot on the end of the hub, ensure that a screw is **NOT** positioned over the keyslot.

5. Slide the reducer onto the shaft at least as far as the counter bore, if present, in the Taper-Grip® bush.

Gradually tighten each screw in turn to the torque levels shown in Table 1. If the shaft has passed through the counter bore, grease fill the cavity at the shaft end to prevent the build up of corrosion. Continue installation from step 3 on page 38.

6. After the reducer has been running for 20 or 30 hours re-torque the screws to the values in Table 1. Screw torques should be subsequently checked at normal service intervals (i.e. every 6 months).

REMOVING THE REDUCER FROM THE SHAFT

Slacken each screw gradually until they are free from the thrust collar.

Give the Taper-Grip® bush a sharp tap with a mallet to break the taper, this will free the reducer. Finger tighten two of the screws against the thrust collar to prevent the Taper-Grip® bush locking in the opposite direction as the reducer is removed from the shaft.

If, as a result of shaft corrosion, the bush is difficult to move, any loose corrosion must first be removed. The reducer can then be withdrawn with the aid of a suitable hub drawer attached to the threaded holes on the Taper-Grip® Bush flange.

Table 1.

HSM Size	Screw size Qty. & Code		Thrust Collar Code	Screw Torque (max) ¹	
				Nm	lb ft
015	6xM10	112B7003	112B6146	40	30
103	6xM10	112B7003	112C6146	50	37

215	6xM16	112G7003	112H6146	300	223
307	8xM16	112G7003	112J6146	300	223
315	10xM16	112G7003	112S6146	300	223
407	12xM16	112S7003	112K6146	250	185
415	12xM16	112S7003	112K6146	250	185
507	15xM16	112S7003	112L6146	250	185
608	20xM16	112S7003	112M6146	250	185

1. Screw torque can be reduced if required output torque is below catalogue rating

IMPORTANT

The reducer is despatched without oil. It must be filled as instructed before running. Use high grade oil as stated below. Fill to level plug when reducer is not running. The approximate quantities are shown in table below. Drain, flush and refill every six months of operation, check oil level regularly. Positions of filler, breather and drain plug for different mounting positions are shown in fig. 4.

CAUTION

Too much oil will cause over-heating. Too little oil will cause gear failure.

Health and Safety at Work Act 1974

Attention is drawn to the "Codes of Practice" issued by oil companies in respect of the handling of their products.

figure 4

▼ Filler plug ◐ Level plug ○ Drain plug

Units are fitted with filler, level and drain plugs generally in position shown.

Approximate oil quantities (litres) Required for different mounting positions (see figure 4)

Unit Size	Approximate Capacity - Litres							
	5:1				13:1, 20:1 & 25:1			
	1	2	3	4	1	2	3	4
015	0.3	0.3	0.3	0.4	0.25	0.4	0.3	0.4
103	0.5	0.5	0.5	0.6	0.4	0.6	0.5	0.6
107	0.8	0.9	0.8	1	0.7	0.9	0.8	0.9
115	1.2	1.7	1.4	1.8	1	1.8	1.4	1.6
203	2.5	2.6	2.4	2.5	2.3	2.6	2.4	2.2
207	3.3	3.2	3.2	3.3	3	3.2	3.2	3.2
215	4.1	5.3	4.1	5.8	3.8	5.5	4.2	5.1
307	5.7	8.6	5.9	8.6	5.4	8.5	5.9	8.3
315	10.9	18.4	13.6	18.4	9.1	16.4	12.6	15.4
407	15.2	21.7	25.2	20.7	12.7	21.7	15.7	19.2
415					12.5	13.5	24.0	11.5
507					22.5	34.5	52.0	27.0
608					36.0	50.0	79.0	45.0

Normal operating positions are shown in fig. 4. Note that the reducer is supplied with four plugs. After the reducer has been mounted in its running position, the plugs must be located as shown in fig. 4 for the appropriate mounting position. If the reducer is not within 20° of one of the positions shown, the oil level plug cannot be safely used to check the oil level. This can be overcome by disconnecting the torque-arm and swinging the reducer around to one of the positions shown.

Because of the many positions of the reducer it may be necessary, or desirable, to make special adaptations using the plug holes in the reducer with standard pipe fitting, standpipes or oil level gauges.

Recommended Mineral Oil Lubricant Viscosities

	Ambient Temp °C	5:1 Ratio Gearbox				13:1, 20:1 & 25:1 Ratio Gearbox				
		0-100	101-200	201-400		0-20	21-50		51-120	
		rev/min	rev/min	rev/min		rev/min	rev/min		rev/min	
		015-407	015-407	015-107	115-407	015-407	015-115	203-407	015-115	203-407

Viscosity	6 to 25	460	320	320	220	680	680	460	460	320
Grade	26 to 40	800	680	680	460	800	800	800	680	460

Sumitomo Cyclo Europe recommends:

Mobil Mobilgear 600 series mineral oil

Mobil SHC XMP 320 synthetic oil is suitable for all ambient temperatures and all input speeds

TO INSTALL BACKSTOP

If reducer is filled with oil, drain off oil before proceeding further.

1. Remove backstop cover ref. 12. Remove all traces of sealant from backstop cover and gear case faces.

2. Determine direction of required shaft rotation.

Sizes 015 & 103

The shaft is free to rotate in the direction of the arrow marked on the backstop cage.

With the backstop cage in the correct orientation, press the backstop into the outer race.

Fit the 'O' ring seal onto the outer race, ensuring the ring is seated fully in the groove. Push the assembly into the housing.

Secure using the screws provided and the lockwashers from the original backstop cover. Finally, after checking for correct shaft rotation, fit the sealing cap into the outer race.

Sizes 107 - 407

Fit the internal circlip into the groove in the outer race.

Slide the 'O' rings over each end of the outer race and ensure both rings are fully engaged in their respective grooves.

Note that on size 315 the two 'O' rings are different diameters.

With the backstop race fitted in the correct direction into the outer race, feed the assembly into the housing, rotating the shaft in its free direction will assist.

When the outer race is fully home, rotate the shaft in its backstopping direction.

If the assembly is correct, the outer race will now rotate with the shaft. Use this feature to align the screw holes.

Place the original backstop cover onto the projecting outer race spigot and secure the complete assembly using the screws provided.

3. Refill the reducer with correct grade of oil.

Note: Do not use E.P. oils other than those recommended when using a backstop.

IMPORTANT

When pushing the backstop assembly into the housing, it is important not to hammer the assembly at any time.

The assembly may be tapped gently if necessary.

To change the backstopping direction at any time, it is necessary to remove the sprag assembly and turn it end for end.

**Sizes 015-103****Sizes 107-407**

TO INSTALL BACKSTOP

If reducer is fitted with oil, drain off oil before proceeding further.

1. Remove backstop cover and recover the gasket (where fitted) ref. 12 & 13 and input bearing distance piece (ref. 88). Refer to Parts Identification section.

2. Marked on the outer race of the backstop is an arrow. This indicates that the input shaft will rotate freely in this direction after the backstop has been installed.

If it is necessary to remove it, turn it end for end, and re-install it. Match the arrow on backstop to direction of rotation desired for the input shaft.

3. Place the two inner race keys (ref. 62) in the input shaft keyways. For ease of installation the backstop, complete with inner race should be pushed into the reducer as a unit.

When pushing backstop into reducer it is important not to hammer on the backstop, but it can be tapped gently if necessary.

Place circlip (ref. 63) into groove in input shaft.

4. Line up keyway in backstop outer race with keyway in backstop housing by rotating the input shaft in the opposite direction to its driving rotation. If the backstop is properly installed it will rotate with the input shaft.

5. Insert key (ref. 61) in the aligned keyways.

6. Replace gasket and backstop cover and refill reducer with oil.

7. Check input shaft for end-float 0.05mm max.

IMPORTANT

If for any reason it is necessary to remove a backstop from an operational unit it is essential that (ref. 88), the input bearing distance piece, is fitted into the vacant backstop housing, and the input shaft end-float checked before restarting the unit.

Note: Do not use E.P. oils other than those recommended when using a backstop.
